

“Real 5G” should be 4.9G

Kazuhiko Goukon
Senior Scientist, Technology Office
Softbank Corporation

Everyone's "5G" is Chitty-Chitty Race SoftBank

>10Gbps /user
(LOS)

=

This cannot be a commercial product!

- **Low bit cost** through mathematical computation strength relaxation
 - Linearly increasing cost along with computation power is horrible
 - Vendor should try to decrease computation power
- **Wide coverage** with improved UL link budget
 - Common channel sweeping should be realized
 - UL is mainly for SRS
 - Time domain SRS power concentration with 1/8 UL/DL ratio.
 - 9dB UL power boost
- **Broadcast channel beamforming**
 - LTE has area limitation with broadcast channel link budget
 - 5G's common channel should be Beamforming somehow
- **User Centric Cell**
- **SDMA**
- **Should fall back and compatible with 4G radio**

These are almost the same as 4G

■ User Centric Cell

- Dedicated Reference Signal tracks UE with beamforming without handover in entire coverage

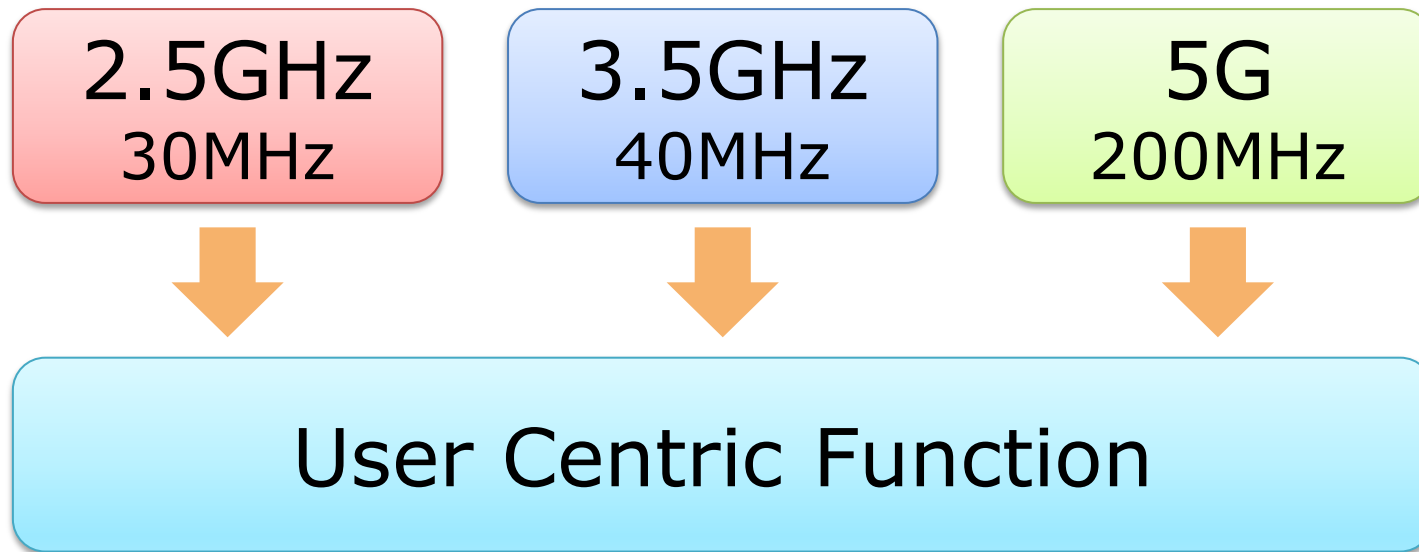

■ SDMA (MU-MIMO)

- Zero-Forcing based interference mitigation Massive MIMO or Distributed MIMO
- SDMA should use channel reciprocity of TDD with SRS from UE

- Aligned with 5G trial in China initiated by CMRI and the vendors
 - China case, 3.5GHz would be used
 - Just changing frequency, nothing other

- Target is
 - Station and NLOS
 - Multi-User Massive MIMO (not single user)
 - User Centric Cell
 - Massive MIMO would eventually achieve 10Gbps/cell capacity

- Every TDD system should go to User Centric
- 5G is just wider band width

SRS Switching (4G/5G) is necessary for Carrier Aggregation

Reciprocal SDMA is key technology of 5G!

TDD can use SRS for uplink channel estimation
Secondary Carrier also needs SRS signal

- Usually LTE network is uplink limited, especially TDD System
- 5G's frequency allocation would be in higher band, that means cell radius would be shrunk

*Coverage of
23dBm UE*

Band 41

*Coverage of
High Power UE*

Band 41

RF Parameter

Frequency : 2555-2575 MHz

(Band 41)

Band width : 20 MHz

Transmit Power : 20W

Cell Parameter

DL-UL ratio : DL / UL= 3 / 1

(Synchronized with commercial
NW)

Surrounded by commercial
network

UE:

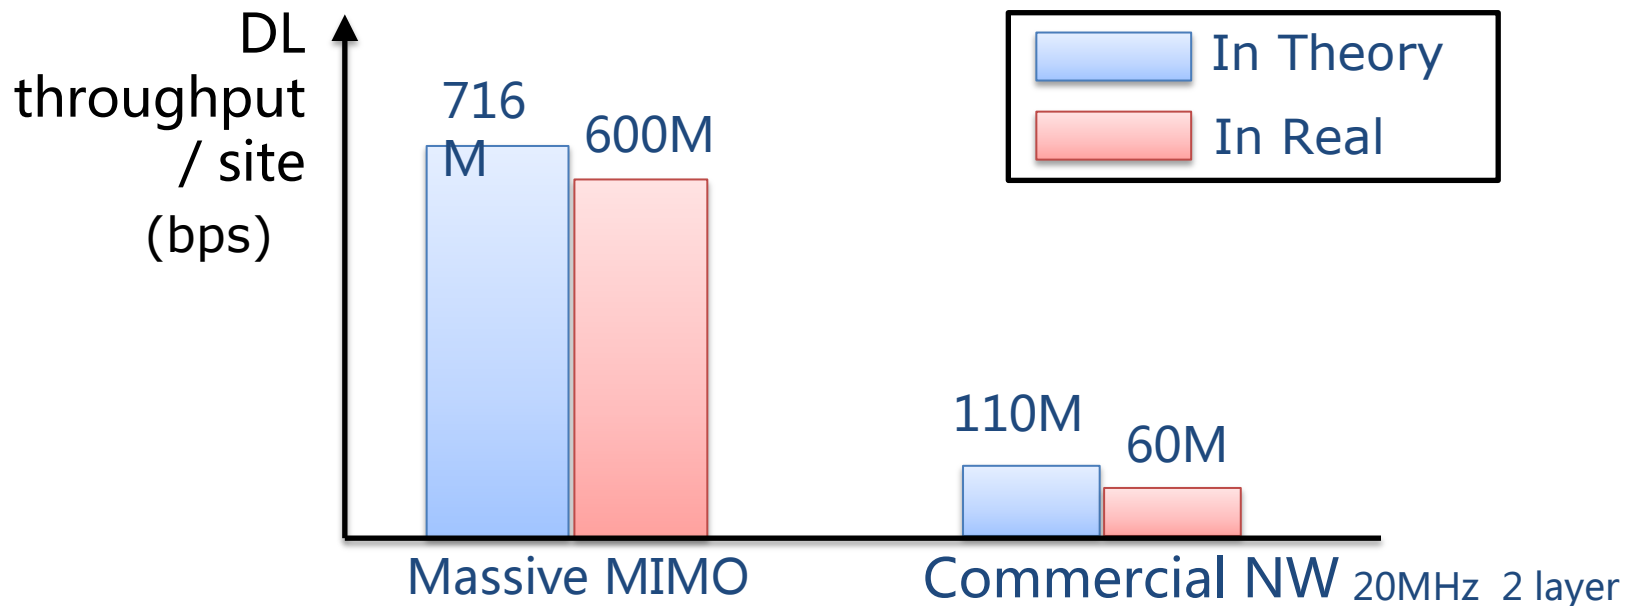

Existing Rel-9 UE

The difference is just bandwidth!

4G (20MHz BW) over 600 Mbps / site

➔ 5G (200MHz BW) over 6 Gbps / site

- We think Massive MIMO is suitable for 3.5GHz, too
- Our 3.5GHz is almost same configuration as 2.5GHz

It should not
be smaller

CPU Interconnect with GPGPU through CMN

- CPU with GPGPU (General-purpose computing on Graphics Processing Units) through CPU interconnect would be essential key for 5G low cost implementation for future high speed BBU
- CPU array and GPGPU array can be inside in one single chip with AMBA (Advanced Microcontroller Bus Architecture) bus
- Already BBU is similar structure but future one would definitely use CPU array + GPGPU array mixed through OpenACC based C++ plus pragma with regular C++ based no stress computing.
- AMBA (Advanced Microcontroller Bus Architecture) and CMN (Coherent Mesh Network) is proprietary technology of ARM
